SEARCH PATTERN ENTRY	6-1
EDIT LINE VALUE Field	6-1
CLEAR PATTERN	6-1
DELETE LINE	6-4
ADD LINE	6-4
LOAD FROM ACTIVE CURSOR	6-4
REFERENCE MEMORY EDITOR	6-5

Press the EDIT key on the front panel to access the Search Pattern Entry and the Reference Memory Editor menus. These menus provide methods for manipulating data in memory.

SEARCH PATTERN ENTRY

A search pattern consists of 1 to 8 lines of data in State Table format. The default pattern is one line with all values set to don't care (X); this setting matches any value, including no data.

The search pattern is used by the pattern highlighting function in the DATA menus. This function operates only if **PATTERN SEARCH ENABLED** is selected in the Search Pattern Entry menu (see callout 3 in Figure 6-1). Whenever the 1240 applies the search pattern to stored data, the message **APPLYING SEARCH PATTERN — PLEASE WAIT** is displayed at the top of the screen. If **PATTERN SEARCH ENABLED** is selected and you make a change to the search pattern then change to another menu, the new pattern is applied. If you do not need the pattern feature, select **PATTERN SEARCH DISABLED**.

Data lines in the pattern are displayed in the center of the menu (see Figure 6-1). Data is displayed according to the output radices specified in the Channel Grouping menu. A horizontal line across the screen marks the location of the "search data cursor" (see callout 6 in Figure 6-1). Move the search data cursor through the pattern with the **SCROLL** knob.

NOTE

The search data cursor is specific to this menu and is not related to the data cursors controlled in the State Table or Timing Diagram.

EDIT LINE VALUE Field. The value of the pattern line at the location of the search data cursor is displayed in the **EDIT LINE VALUE** field (see callout 5 in Figure 6-1). Data in these fields is displayed using input radices. If the input and output radices for a group are different, the text displayed in the **EDIT LINE** and at the location of the search data cursor will be different even though the value is the same.¹

Use the data entry keys to modify the data in the **EDIT LINE** as required. As you enter changes, the pattern line at the location of the search cursor is updated.

The **ENTER DATA FOR** field (see callout 4 in Figure 6-1) controls the timebase(s) associated with the **EDIT LINE VALUE**. This field is only displayed if both timebases T1 and T2 are active. Selections are **T1 ONLY**, **T2 ONLY**, and **T1 AND T2**. As you move the search data cursor, this field is updated to reflect the timebase(s) associated with each pattern line. For example: if you move the search data cursor to a pattern line with both T1 and T2 data, this field displays **T1 AND T2**. If you then change this field to **T1 ONLY**, the data for groups associated with T2 is deleted from the **EDIT LINE VALUE**.

With certain grouping setups, all channels cannot be displayed on the **EDIT LINE** at once. The truncation symbol (▶) will be displayed. Move the truncated channels onto the screen with the cursor keys. If the search pattern lines are truncated, you must change the display radix of one or more channel groups to see the truncated data.

The \$ symbol is displayed in the **EDIT LINE** if glitch and non-glitch channels are combined into one digit of the input radix.

CLEAR PATTERN. Touch this soft key to return the search pattern to the default setup: one line with all values set to don't care. When you touch this soft key, **PRESS 'X' TO CONFIRM OPERATION (ANY OTHER HARD KEY CANCELS IT)** is displayed at the top of the screen. The pattern is not cleared until you press the X key on the front panel.

¹ Octal-Hex-ASCII and Octal-Hex-EBCDIC conversion charts are included in Section 8.

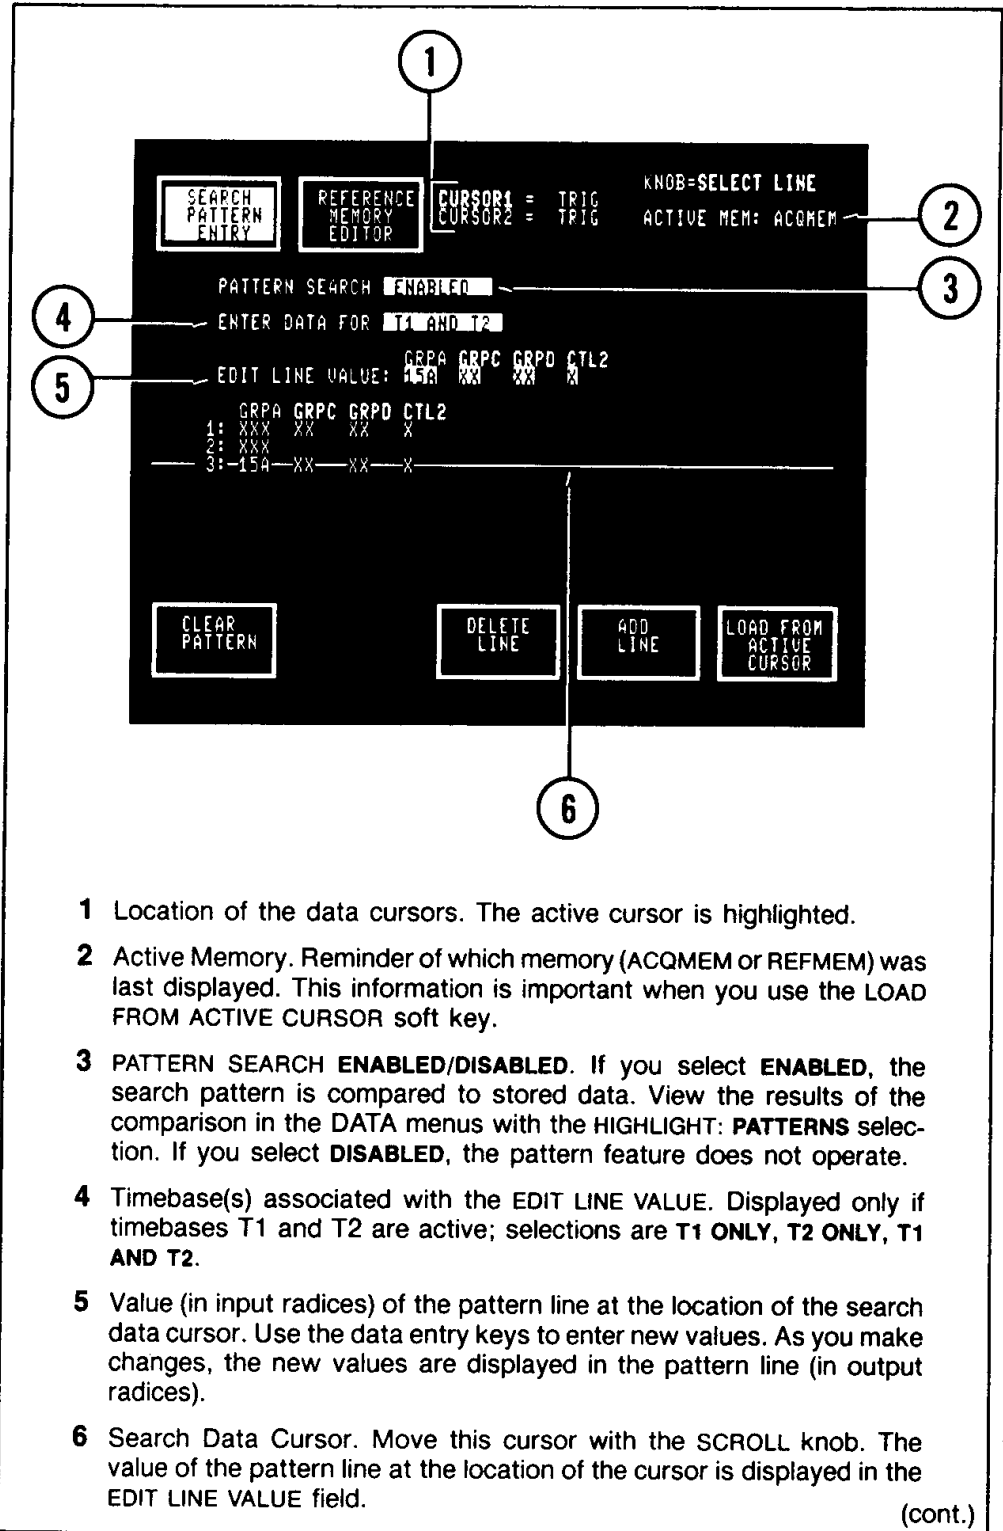

Figure 6-1. Sample Search Pattern Entry menu display. A search pattern consists of 1 to 8 lines of data in State Table format. The pattern in this display will match any three consecutive memory locations where the second location has only T1 data, and the third location has 15A in GRPA.

(cont.)

The screenshot shows a terminal-style interface for editing search patterns. At the top, there are menu options: **SEARCH PATTERN ENTRY**, **REFERENCE MEMORY EDITOR**, **CURSOR1 = TRIG**, **CURSOR2 = TRIG**, **JOB=SELECT LINE**, and **ACTIVE MEM: ACQMEM**. Below these, it indicates **PATTERN SEARCH ENABLED** and prompts to **ENTER DATA FOR T1 AND T2**. The **EDIT LINE VALUE:** section shows fields for **GRPA**, **GRPC**, **GRPD**, and **CTL2**, with values like **15A**, **XX**, **XX**, and **X**. A list of three pattern lines follows: **1: XXX XX XX X**, **2: XXX**, and **3: -15A-XX-XX-X**. The third line is highlighted. At the bottom, there are four buttons: **CLEAR PATTERN**, **DELETE LINE**, **ADD LINE**, and **LOAD FROM ACTIVE CURSOR**. Callouts 7 through 14 point to specific elements: 7 points to the highlighted fields in the edit line value; 8 points to the third pattern line; 9 points to the first pattern line; 10 points to the second pattern line; 11 points to the CLEAR PATTERN button; 12 points to the DELETE LINE button; 13 points to the ADD LINE button; and 14 points to the LOAD FROM ACTIVE CURSOR button.

7 Group names. Groups associated with timebase T2 are highlighted.

8 This pattern line matches any value, including no data.

9 This pattern line matches any memory location with only T1 data; it will not match any location with T2 data.

10 This line matches any memory location with the specified T1 data. The pattern will not match if this location does not immediately follow a location with only T1 data (see callout 9).

11 Returns the search pattern to the default setup: one line with all values set to don't care. PRESS "X" TO CONFIRM OPERATION (ANY OTHER HARD KEY CANCELS IT) is displayed at the top of the screen when you touch this soft key. The pattern is not cleared until you press the X key.

12 Deletes the line at the location of the search data cursor.

13 Adds a new line to the pattern below the position of the search data cursor. The new line has the same data as the preceding line. The search data cursor moves down to the new line.

14 Loads the EDIT LINE VALUE with the same data as the location in active memory where the active data cursor is positioned.

EDIT—1240 Operator's

DELETE LINE. Touch this soft key to delete the line at the location of the search data cursor. Deleting the only line in a pattern is the same as touching the CLEAR PATTERN soft key.

ADD LINE. Touch this soft key to add a new line to the pattern below the position of the search data cursor. The new line will have the same data as the preceding line. The search data cursor moves down to the new line and its value appears in the EDIT LINE.

LOAD FROM ACTIVE CURSOR. Touch this soft key to load the EDIT LINE with the same data as the location in active memory where the active data cursor is positioned. Active memory is the type of memory last displayed. For example: if you want a value from reference memory to be part of the pattern, the active data cursor must be positioned on that location and reference memory must be the last memory displayed. A line at the top of the menu shows whether acquisition memory (ACQMEM) or reference memory (REFMEM) is active (see callout 2 in Figure 6-1). The cursor display at the top of the menu shows the locations of data cursors 1 and 2; the active cursor is highlighted. (Refer to Section 5 for a complete description of the data cursors.)

This operation lets you build patterns from data in memory without writing down or trying to remember the data. (Select PATTERN SEARCH **DISABLED** while you are building the pattern to keep the pattern from being applied every time you switch to the DATA displays to move the active data cursor. Enable pattern search when the pattern is complete.)

REFERENCE MEMORY EDITOR

Use this menu to change data values in reference memory. You can also move the trigger event to a different location. It is not possible to add or delete locations, change channel values to don't care, or change the number or type of timebases for which data is valid.

Reference memory locations are displayed in the center of the menu ² (see Figure 6-2) using the output radices specified in the Channel Grouping menu. Only locations around the active data cursor are displayed. The active cursor is controlled in this menu just like it is in the State Table or Timing Diagram: move the cursor with the SCROLL knob, and change the active role to the other cursor with the CHANGE ACTIVE CURSOR soft key. The cursor display at the top of the menu shows the locations of cursors 1 and 2 and the distance between them (CURSOR Δ);³ the active cursor is highlighted.

The EDIT LINE VALUE (see callout 1 in Figure 6-2) shows the value of the memory location at the position of the active cursor. The value is displayed in the input radices specified for each group. If the input and output radices are different for a channel group, the text for that group in the EDIT LINE VALUE will be different from the text shown in the memory location, even though the value is the same.

Use the data entry keys to make changes in the EDIT LINE VALUE. As you make changes, the location in reference memory is updated. Don't care (X) is not a valid entry. The glitch symbol (\blacklozenge) is valid only for 9-channel card groups assigned T1 ASYNC, and when glitch storage is enabled in the Memory Config menu.

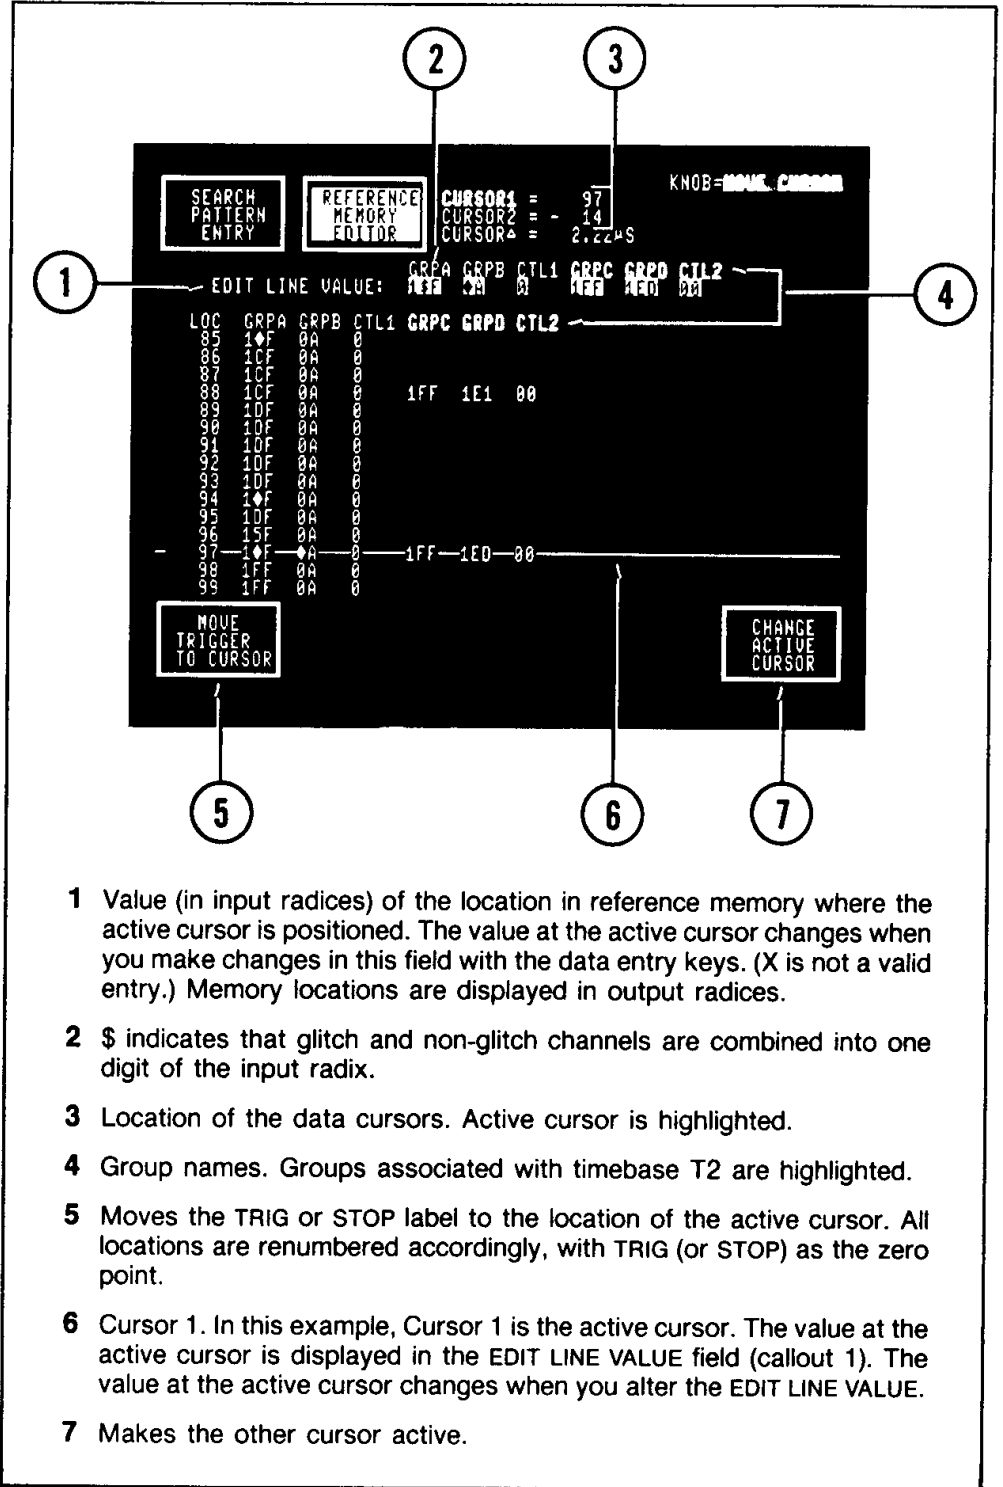

With certain grouping setups, all channels cannot be displayed on the EDIT LINE VALUE at once. The truncation symbol (\blacktriangleright) will be displayed. Move the truncated channels onto the screen with the cursor keys. If the reference memory data is truncated, you must change the display radix of one or more channel groups to see the truncated data.

The MOVE TRIGGER TO CURSOR soft key transfers the TRIG or STOP ⁴ label to the location of the active cursor. The new TRIG or STOP location is the zero point, and all other locations are renumbered accordingly. This operation does not rearrange memory locations; it renumbers them from a new starting point. This feature is useful when you want to change the trigger to other data in reference memory, then use the COMPARE ACQMEM TO REFMEM Auto-Run condition to compare data around the new trigger. It is also useful when you want to highlight memory differences with the memories aligned at a new location.

² Reference memory is not displayed if the memory width vs. depth and pod-timebase selections in effect when the memory was stored are not the same as the selections in the current setup. Refer to *Memory Configuration Requirements* in Section 5 for more information.

³ Refer to *Data Scrolling and Cursor Control* in Section 5 for more information about CURSOR Δ .

⁴ If you press the STOP key before the trigger occurs, the last location in acquisition memory is labeled STOP.

4340-48

Figure 6-2. Sample Reference Memory Editor menu display. This menu displays reference memory in State Table format. The EDIT LINE VALUE field lets you change the data at the location of the active cursor.
